- Coverage
- Precision
- Bias?
- Accuracy?

Coverage

If you use your fitting algorithm on simulations from your model world, then you know the right answer!

- The right answer should be inside your 95% confidence interval 95% of the time
 - If more, your model is too conservative
 - If less, your model is invalid

Precision

 You should aim to make your confidence intervals as narrow as possible

(ロ) (同) (三) (三) (三) (○) (○)

- Provide as much information as possible
- As data increases, your precision should increase
 - Cls should approach zero width

Bias?

- Nobody wants to be biased
- You need to be asymptotically unbiased
 - Good coverage and good precision assure this
- Not so clear you need to be *absolutely* unbiased
 - Bias is the difference between the *mean* expected prediction and the true value
 - Scale dependent: an unbiased estimate of *γ* is automatically a biased estimate of *D* (but not asymptotically biased)

(日) (日) (日) (日) (日) (日) (日)

Maybe the median would be a better measure

Accuracy?

- Nobody wants to be inaccurate
- Good coverage and good precision should guarantee good accuracy

Model Evaluation

Goodness of fit Capturing patterns Going beyond

Conclusion

・ロト・日本・日本・日本・日本・日本

Goodness of fit

- Goodness of fit statistics describe how well a model prediction matches observed data
- Goodness of fit tests attempt to determine whehter the observed difference between model and data is statistically significant

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Your model is false!

- A goodness of fit test won't make it true
- You can "pass" a goodness of fit test by:
 - having a good model
 - having bad data
 - choosing an inappropriate way to compare
- So why do we use P values at all in biology?

Vitamin study

Low P values

High P values

Goodness of fit test

- Your model is not reality (null hypothesis is false)
- Can we see the difference clearly?
 - If no, model may be good or bad.
 - We probably can't add any more complexity based on current data
 - If yes, model may be good or bad. We may be able to add more complexity based on current data

(ロ) (同) (三) (三) (三) (○) (○)

But we may not need to

Goodness of fit Capturing patterns Going beyond

Conclusion

・ロト・日本・日本・日本・日本・日本

Capturing patterns

- You can ask:
 - Does your model do a reasonable job of capturing the data?
 - You can use a goodness of fit statistic for this, and not worry about the P value

(ロ) (同) (三) (三) (三) (○) (○)

Does your model capture patterns and relationships that you (or other experts) think are important?

Outline

Conceptual models

Prediction

Model Validation

Model Evaluation

Goodness of fit Capturing patterns Going beyond

Conclusion

・ロト・日本・日本・日本・日本・日本

Out-of-sample validation

- Does your model make predictions *outside* the range on which you calibrated it?
 - Predicting gravitational shifts in star positions from measurements in Earth laboratories
 - Predicting cholera outbreaks in Bangladesh from a model calibrated to Haiti

(ロ) (同) (三) (三) (三) (○) (○)

 Predicting influenza patterns in 2010 from a model calibrated from 2000–2009

Test sets

- What is test set spelled backwards?
- Hold some data out while fitting your model
- Or just pretend to do this as an evaluation method
 - In other words, test what would happen under various withholding scenarios

(ロ) (同) (三) (三) (三) (○) (○)

Other model worlds

- The model you're *fitting* is probably pretty simple
- But you can *simulate* very complicated models, indeed

How well can you do? Which details are important?

<ロ> < 団> < 団> < 豆> < 豆> < 豆</p>

Dynamic models can help:

- Think clearly
- Understand outcomes
- Predict outcomes
- Find new mechanisms

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

Evaluation

- Validation (inside your model world)
- Inspection (compare patterns)
- Prediction (and other out-of-sample comparison)

(ロ) (同) (三) (三) (三) (○) (○)

Generate and test hypotheses

Conclusion

Essentially, all models are wrong, but some are useful. – Box and Draper (1987), *Empirical Model Building*
